

### Overview

### Features

- Quad switch driver
- Free configurable as bridge or quad-switch
- Optimized for DC motor management applications
- Ultra low  $R_{DS\ ON}$  @ 25 °C:
  - High-side switch: typ. 85 mΩ,
  - Low-side switch: typ. 40 mΩ
- Very high peak current capability
- Very low quiescent current
- Space- and thermal optimized power P-DSO-Package
- Load and GND-short-circuit-protected
- Operates up to 40 V
- Status flag diagnosis
- Overtemperature shut down with hysteresis
- Short-circuit detection and diagnosis
- Open-load detection and diagnosis
- C-MOS compatible inputs
- Internal clamp diodes
- Isolated sources for external current sensing
- Over- and under-voltage detection with hysteresis

### Description

The **BTS 771** is a TrilithIC contains one double high-side switch and two low-side switches in **one P-DSO-28-9** -Package.

**“Silicon instead of heatsink”**  
**becomes true**

The ultra low  $R_{DS\ ON}$  of this device avoids powerdissipation. It saves costs in mechanical construction and mounting and increases the efficiency.

The high-side switches are produced in the **SIEMENS SMART SIPMOS®** technology. It is fully protected and contains the signal conditioning circuitry for diagnosis. (The comparable standard high-side product is the **BTS 621L1**.)

---

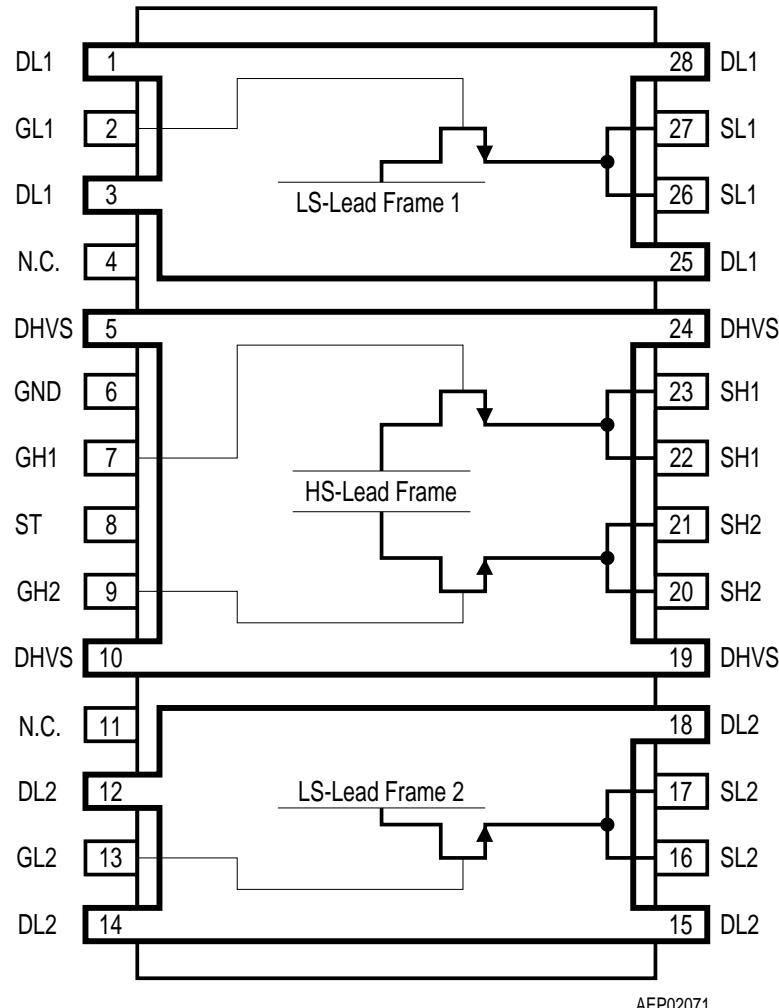

For minimized  $R_{DS\ ON}$  the two low-side switches are produced in the **SIEMENS Millifet** logic level technology (The comparable standard product is the **BUZ 103AL**).

Each drain of these three chips is mounted on separated leadframes (see **P-DSO-28-9** pin configuration). The sources of all four power transistors are connected to separate pins.

So the **BTS 771** can be used in H-Bridge configuration as well as in any other switch configuration.

Moreover, it is possible to add current sense resistors.

All these features open a broad range of automotive and industrial applications.

## Circuit Description

### Input Circuit

The control inputs GH1,2 consist of TTL/CMOS compatible Schmitt-Triggers with hysteresis. Buffer amplifiers are driven by these stages and convert the logic signal into the necessary form for driving the power output stages.

The inputs GH1 and GH2 are connected to a standard N-channel logic level power-MOS gate.

### Output Stages

The output stages consist of an ultra low  $R_{DS\ ON}$  Power-MOS H-Bridge. Protective circuits make the outputs short circuit proof to ground and load short circuit proof. Positive and negative voltage spikes, which occur when driving inductive loads, are limited by integrated power clamp diodes.

### Short Circuit Protection (valid only for the high-side switches)

The outputs are protected against

- output short circuit to ground, and
- overload (load short circuit).

An internal OP-Amp controls the Drain-Source-Voltage of the HS-Switches by comparing the DS-Voltage-Drop with an internal reference voltage. Above this trippoint the OP-Amp reduces the output current depending on the junction temperature and the drop voltage.

In the case of overloaded high-side switches the status output is set to low.

If the HS-Switches are in OFF-state-Condition internal resistors Ro1,2 from SH1,2 to GND pull the voltage at SH1,2 to low values. On each output pin SH1 and SH2 an output examiner circuit compares the output voltages with the internal reference voltage VEO. This results in switching the status output to low. In H-Bridge condition this feature can be used to protect the low-side switches against short circuit during the OFF-period.

### Overtemperature Protection (valid only for the high-side-switches)

The chip also incorporates an overtemperature protection circuit with hysteresis which switches off the output transistors and sets the status output to low.

### Undervoltage-Lockout (UVLO)

When  $V_s$  reaches the switch-on voltage  $V_{UVON}$  the IC becomes active with a hysteresis. The High-Side output transistors are switched off if the supply voltage  $V_s$  drops below the switch off value  $V_{UVOFF}$ .

### **Overvoltage-Lockout (OVLO)**

When  $V_S$  reaches the switch-off voltage  $V_{OVOFF}$  the High-Side output transistors are switched off with a hysteresis. The IC becomes active if the supply voltage  $V_S$  drops below the switch-on value  $V_{OVON}$ .

### **Open Load Detection**

Open load is detected by current measurement. If the output current drops below an internal fixed level the error flag is set with a delay.

### **Status Flag**

Various errors as listed in the table “Diagnosis” are detected by switching the open drain output ST to low.

**Truthtable and Diagnosis (valid only for the High-Side-Switches)**
