## UM6502/07/12 <br> 8-bit Microprocessor

## Features

- Single $5 \mathrm{~V} \pm 5 \%$ power supply
- N channel, silicon gate, depletion load technology
- 56 instructions
- Decimal and binary arithmetic
- Thirteen addressing modes
- True indexing capability
- Programmable stack pointer
- Variable length stack
- Interrupt capability
- Non-maskable interrupt
- Bi-directional data bus
- Addressable memory range of up to 64 K bytes
- "Ready" input
- Direct memory access capability
- Bus compatible with MC6800
- Choice of external or an-board clocks
- $1 \mathrm{MHz}, 2 \mathrm{MHz}, 3 \mathrm{MHz}$ and 4 MHz versions
- On-chip clock options
-External single clock input
-Crystal time base input
- Pipeline architecture
single phase inputs or crystals provide the time base. The UM6512 external clock version is geared to multiprocessor system applications where maximum timing control is mandatory. These products are bus compatible with the MC6800.

## General Description

The UM6502/UM6507/UM6512 microprocessors are totally software compatible with one another. These products provide a wide selection of addressable memory range, interrupt input options and on-chip clock oscillators and drivers. The UM6502/UM6507 on-chip clock versions are aimed at high performance, low cost applications where

## Absolute Maximum Ratings*

| Supply Voltage $\mathrm{V}_{\text {cc }}$ | -0.3 to +7.0 V |
| :---: | :---: |
| Input Voltage $\mathrm{V}_{\text {IN }}$ | -0.3 to +7.0V |
| Operating Temperature $T_{A}$ | $\cdots .0$ to $70^{\circ} \mathrm{C}$ |
| Storage Temperature TSTG $^{\text {S }}$ | -55 to $+150^{\circ} \mathrm{C}$ |

## "Comments

Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only. Functional operation of this device at these or any other conditions above those indicated in the operational sections of this specification is not implied and exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## Notes:

1. CLOCK GENERATOR IS NOT INCLUDED ON UM6512
2. ADDRESSING CAPABILITY AND CONTROL OPTIONS VARY WITH EACH PRODUCT

Notes:

1. Measured between $10 \%$ and $90 \%$ points.
2. Measured at $50 \%$ point.
3. Load $=1 \mathrm{TTL}$ load +30 pF .
4. ROY must never switch states within $\mathrm{T}_{\text {RS }}$ to end of $\boldsymbol{\phi}_{2}$.
5. Load $=100 \mathrm{pF}$.
6. The 2 MHz devices are identified by an " $A$ " suffix.
7. The 3 MHz devices are identified by a " $B$ " suffix.
8. The 4 MHz devices are identified by a " C " suffix.

## Timing Diagram Nota:

Because the clock generation for the UM6502/UM6507 and UM6512 is different, the two clock timing sections are referenced to the main timing diagram by three reference lines marked REF ' $A$ ', REF ' $B$ ' and REF ' $C$ '. Reference between the two sets of clock timings is without meaning. Timing parameters referring to these line and scal variations in the diagrams are of no consequence.

## Pin Description

Clocks ( $\phi_{1}, \phi_{2}$ )
The UM6512 requires a two phase non-overlapping clock that runs at the $\mathrm{V}_{\mathrm{CC}}$ voltage level.
The UM6502/UM6507 clocks are supplied with an internal clock generator. The frequency of these clocks is externally controiled. Clock generator circuits are shown elsewhere in this data sheet.

Address Bus $\left(A_{0} \cdot A_{15}\right)$
(See sections on each micro for respective address lines on these devices.)
These outputs are TTL compatible, capable of driving one standard TTL load and 130 pF .

## Data Bus ( $\mathrm{DB}_{0}-\mathrm{DB}_{7}$ )

Eight pins are used for the data bus. This is a bidirectional bus, transferring data to and from the device and peripherals. The outputs are three-state buffers, capable of driving one standard TTL load and 130 pF .

## Date Bus Enable (DBE)

This TTL compatible input allows external control of the three-state data output buffers and will enable the microprocessor bus driver when in the high state. In normal operation DBE would be driven by the phase two $\left(\boldsymbol{\phi}_{2}\right)$ clock. thus allowing data output from the microprocessor only during $\boldsymbol{\phi}_{2}$. During the read cycle, the data bus drivers are internally disabled, becoming essentially an open circuit. To the disable the data bus drivers externally, DEB should be held low. This signal is available on the UM6512 only.

## Roady (RDY)

This input signal allows the user to halt the microprocessor on all cycles except write cycles. A negative transition to the low state during or coincident with phase one, $\left(\phi_{1}\right)$ will halt the microprocessor with the output address lines reflecting the current address being fetched. This condition will remain through a subsequent phase two $\left(\phi_{2}\right)$ in which the Ready signal is low. This feature allows microprocessor interfacing with low speed PROMs as well as fast (max. 2 cycle) Direct Memory Access (DMA). If ready is low during a write cycle, it is ignored until the following read operation. Ready transitions must not be permitted during $\phi_{2}$ time.

## Interrupt Request (IRZ)

This TTL level input requests that an interrupt sequence begin within the microprocessor. The microprocessor will complete the current instruction being executed before recognizing the request. At the time, the interrupt mask bit in the Status Code Register will be examined. If the interrupt mask flag is not set, the microprocessor will begin an interrupt sequence. The Program Counter and Processor Status Register are stored in the stack. The microprocessor will then set the interrupt mask flag high so that no futher interrupts may occur. At the end of this cycle, the program counter low will be loaded from address FFFE, and program counter high from location FFFF, therefore transferring program control to the memory vector located at these addresses. The ROY signal must be in the high state for any interrupt to be recognized. A $3 \mathrm{~K} \Omega$ external resistor should be used for proper wire-OR operation.

## Non-Mackable Interrupt (NWTI)

A negative going transition on this input requests that a non-maskable interrupt sequence be generated within the microprocessor.
$\overline{\text { NMI }}$ is an unconditional interrupt. Following completion of the current instruction, the sequence of operations defined for IRQ will be performed, regardless of the state interrupt mask flag. The vector address loaded into the program counter, low and high, are locations FFFA and FFFB respectively, thereby transferring program control to the memory vector located at these addresses. The instructions loaded at these locations cause the microprocessor to branch to a non-maskable interrupt routine in memory.
$\overline{\mathrm{NMI}}$ also requires an external $3 \mathrm{~K} \Omega$ resistor to $\mathrm{V}_{\mathrm{CC}}$ for proper wire-OR operations.
inputs $\overline{\mathrm{RO}}$ and $\overline{\mathrm{NMI}}$ are hardware interrupt lines that are sampled during $\phi_{2}$ (Phase 2) and will begin the appropriate interrupt routine on $\phi_{1}$ (phase 1 ) following the completion of the current instruction.

## Set Overflow Flag (S. O.)

A NEGATIVE going edge on this input sets the overflow bit in the Status Code Register. This signal is sampled on the trailing edge of $\phi_{1}$.

## SYNC

This output line is provided to identify those cycles in which the microprocessor is doing an OP CODE fetch. The SYNC line goes high during $\phi_{1}$ of an OPCODE fetch and stays high for the remainder of that cycle. If the RDY line is pulled low during the $\phi_{1}$ clock pulse in which SYNC went high, the processor will stop in its current state and will "remain in the state until the RDY line goes high. In this manner, the SYNC signal can be used to control RDY to cause single instruction execution.

## Reset (RES)

This input is used to reset or start the microprocessor from a power down condition. During the time that this line is held low, writing to or from the microprocessor is inhibited. When a positive edge is detected on the input, the microprocessor will immediately begin the reset sequence.
After a system initlalization time of six clock cycles, the mask interrupt flag will be set and the microprocessor will laad the program counter from the memory vector locations FFFC and FFFD. This is the start location for program control.

After $V_{C C}$ reaches 4.75 volts in a power up routine, reset must be held low for at least two clock cycles. At this time the $\mathrm{R} / \bar{W}$ and SYNC signal will become valid. When the reset signal goes high following these two clock cycles, the microprocessor will proceed with the normal reset procedure detalled above.

## Read/Write (R/W)

This output signal is used to control the direction of data transfers between the processor and other circuits on the data bus. A high level on $R / \bar{W}$ signifies data into the processor; a low is for the data transfer out of the processor.

## Programming Charactaristics

INSTRUCTION SET - ALPHABETIC SEQUENCE

| ADC | Add Memory to Accumulator with Carry | LDA | Load Accumulator with Memory |
| :---: | :---: | :---: | :---: |
| AND | "AND" Memory with Accumulator | LDX | Load Index $X$ with Mernory |
| ASL | Shift left One Bit (Memory or Accumulator) | LOY | Load Index $Y$ with Memory. |
|  |  | LSA | Shift One Bit Right (Mermory or Accumulator) |
| BCC | Branch on Carry Clear |  |  |
| BCS | Branch on Carry Set | NOP | No Operation |
| BEQ | Branch on Result Zero | ORA | "OR" Memory with Accumulator |
| BIT | Test Bits in Memory with Accumulator | ORA | OR Memory with Accumulator |
| BMI | Branch on Result Minus | PHA | Push Accumulator on Stack |
| BNE | Branch on Result not Zero | PHP | Push Processor Status on Stack |
| BPL | Branch on Result Plus | PLA | Pull Accumulator from Stack |
| BNK | Force Break | PLP | Pull Processor Status from Stack |
| BVC | Branch on Overflow Clear |  |  |
| BVS | Branch on Overflow Set | ROL | Rotate One Bit Left (Memory or Accumulator) |
| CLC | Clear Carry Flag | ROR | Rotate One Bit Right (Memory or Accumulator) |
| CLD | Clear Decimal Mode | RTI | Return from Interrupt |
| CLI | Clear Interrupt Disable Bit | RTS | Return from Subroutine |
| CLV | Clear Overflow Flag |  |  |
| CMP | Compare Memory and Accumulator | SBC | Subtract Memory from Accumulator with |
| CPX | Compare Memory and Index X |  | Borrow |
| CPY | Compare Memory and Index $Y$ | SEC | Set Carry Flag |
|  |  | SED | Set Decimal Mode |
| DEC | Decrement Memory by One | SEI | Set Interrupt Disable Status |
| DEX | Decrement Index $X$ by One | STA | Store Accumulator in Memory |
| DEY | Decrement Index Y by One | STX | Store Index $X$ in Memory |
| EOR | "Exclusive-or" Memory with Accumulator | STY | Store Index Y in Memory |
| INC | Increment Memory by One | TAX | Transfer Accumulator to Index $X$ |
| INX | Increment Index X by One | TAY | Transfer Accumulator to Index $Y$ |
| INY | Increment Index Y by One | TSX | Transfer Stack Pointer to Index $X$ |
|  |  | TXA TXS | Transfer Index $X$ to Accumulator |
| JMP | Jump to New Location Jump to New Location Saving Return Address | TYA | Transfer Index $Y$ to Accumulator |

## ADDRESSING MODES

## Aceumulator Addressing

This form of addressing is represented with a one byte instruction, implying an operation on the accumulator.

## Immediate Addressing

In immediate addressing, the operand is contained in the second byte of the instruction, with no further memory addressing required.

## Absolute Addressing

In absolute addressing, the second byte of the instruction specifies the eight low order bits of the effective address whille the third byte specifies the eight high order bits. Thus, the absolute addressing mode allows access to the entire 65 K bytes of addressable memory.

## Zoro Pegs Addressing

The zero page instructions allow for shorter code and execution times by only fetching the second byte of the instruction and assuming a zero high address byte. Careful use of the zero page can result in significant increase in code efficiency.

## Indexed Zoro Pago Addressing - (X, Y indoxing)

This form of addressing is used in conjunction with the index register and is referred to as "Zero Page, $X$ " or "Zero Page, Y." The effective address is calculated by adding the second byte to the contents of the index register. Since this is a form of "Zero Page" addressing, the content of the secondbyte references a location on page zero. Additionally, due to the "Zero Page" addressing
nature of this mode, no carry is added to the high order 8 -bits of memory and crossing of page boundaries does not occur.

## Indexed Absolute Addressing - (X,Y indexing)

This form of addressing is used in conjunction with the $X$ and $Y$ index registers and is referred to as "Absolute, $X$." and "Absolute, $Y$ " The effective address is formed by adding the contents of $X$ or $Y$ to the address contained in the second and third bytes of the instruction. This mode allows the index register to contain the index, or count value, and the instruction to contain the base address. This type of indexing allows any location reference and the index to modify multiple fields, resulting in reduced coding and execution time.

## Implied Addressing

In the implied addressing mode, the address containing the operand is implicitly stated in the operation code of the instruction.

## Relative Addressing

Relative addressing is used only with branch instructions and establishes a destination for the conditional branch.

The second byte of the instruction becomes the operand which is an "Offset" added to the contents of the lower eight bits of the program counter when the counter is set to the next instruction. The range of the offset is-128 to +127 bytes from the next instruction.

## Indexed Indirect Addressing

In indexed indirect addressing (referred to as "Indirect, $\left.X^{\prime \prime}\right)$, the second byte of the instruction is added to the contents of the X index register, discarding the carry. The result of this addition points to a memory location on page zero whose contents is the low order eight bits of the effective address. The next memory location on page zero contains the high order eight bits of the effective address. Both memory locations specifying the high and low order bytes of the effective address must be on page zero.

## Indirect Indexed Addressing

In indirect indexed addressing (referred to as "Indirect, $Y$ ' 1 . the second byte of the instruction points to a memory location on page zero. The contents of this memory location is added to the contents of the $Y$ index register, the result being the low order eight bits of the effective address. The carry from this addition is added to the contents of the next page zero memory location, the result being the high order eight bits of the effective address.

## Absolute Indirect

The second byte of the instruction contains the low order eight bits of a memory location. The high order eight bits of that memory location is contained in the third byte of the instruction. The contents of the fully specified memory location is the low order byte of the effective address. The next memory location contains the high order byte of the effective address which is loaded into the sixteen bits of the program counter.

## PROGRAMMING MODEL

## Clock Generation Circuits"
